Preface

This is a personal documentation and notebook for the first course in programming at the Lucerne University of Applied Sciences and Arts. The goal of this document is to collect useful informations and nice snippets of code out of the course.

This document shall not be provided as a official or unofficial cheatsheet for the course exam or similar.

1 Objects and classes

1.1 Summary exercises

Exercise 1.31

What are the types of the following values?

```
0 short, char, byte, int, long
"hello" String
101 short, char, byte, int, long
-1 int, char, byte, int, long
true boolean
"33" String
3.1415 float, double
```

Exercise 1.32

What would you have to do to add a new filed, for example one called name, to a circle object?

```
private String name;
```

Exercise 1.33

Write the signature of a method named send that has one parameter of type String, and does not return a value.

```
public void send(String foo)
```

Exercise 1.34

Write a signature for a method named average that has two parameters, both of type int, and returns an int value.

```
public int average(int foo, int bar)
```

Exercise 1.35

Look at the book you are reading right now. Is it an object or class? If it is a class, name some objects. If it is an object, name its class.

The book is definitely an object, because it's a specific thing and in no way generic. The class could have a name like SchoolBook, CodingBook or just Book.

Exercise 1.36

Can an object have several different classes? Discuss.

No it can't.

2 Understanding class definitions

2.1 Start with Eclipse

In the first chapter we've worked with the BlueJ IDE but now I want to check Java-Coding with a common and popular Java-IDE like Eclipse To get the BlueJ-Projects work with Eclipse there are some things that have to be done.

- 1. Create a new project in Eclipse.
- 2. Import the source (BlueJ example-code).
- 3. Add a package-name to the source.
- 4. Create a main (replaces all interaction which were invoked by hand).

Listing 1: TicketMachine

```
package foobar;

public class TicketMachine
{
    // The price of a ticket from this machine.
    private int price;
    // The amount of money entered by a customer so far.
    private int balance;
```

Listing 2: Main (TicketMachine)

```
package foobar;

public class Main
{
    public static void main(String[] args)
    {
        TicketMachine tml;
        tml = new TicketMachine(300);

        tml.insertMoney(200);

        System.out.println("Balance: "+tml.getBalance());

        tml.insertMoney(100);

        tml.printTicket();
    }
}
```

2.2 Chapter Exercises

Exercise 2.21

Suppose that the class Pet has a field called name that is of type String. Write an assignment statement in the body of the following constructor so that the name field will be initialized with the value of the constructor's parameter.

```
public Pet(String petsName)
{
    name = petsName;
}
```

Exercise 2.22 (challenge)

The following object creation will result in the constructor of the Date class being called. Can you write the constructor's header?

```
new Date("March", 23, 1861)
```

Try to give meaningful names to the parameters.

```
public Date(String month, int day, int year)
{
    ...
}
```

2.3 Selfstudy-Questions OOP2

Exercise 4

A class is build by three essential components. What are they?

- Instance variables (member variables, attributes)
- constructor
- methods

Exercise 5

What is the order of the three components?

The order doesn't matter technically but there is a common convention:

- 1. instance variables
- 2. constructor
- 3. methods

Exercise 6

What's their purpose?

instance variables are holding data of an object. All of this data together builds the object's state. constructor is a special method that initializes objects.

methods are sequences which are defining the object's behaviour and characteristics.

Exercise 8

What is a variable?

A variable (or field) is a data storage inside an object that can be used for persistent data storage (limited by the lifetime of the object).

Exercise 9

What are the synonyms to instance variables?

- member variable
- attribute
- filed
- variable

Exercise 10

What do you think where the term instance variable comes from?

An instance is a realisation of an class by an object. The expression variable is well defined an known in computer science and if a variable explicitly belongs to an object, so it's clear that this is a variable of an instance or instance variable.

Exercise 11

How can you put comments into a Java-Code?

There are different ways to add comments in a Java source file without having trouble with the compiler.

• Use the single line comment by double slash.

```
// this method return the speed
private void getSpeed()
```

• Use the multiline comment by slash-dot

```
/**

* This is a method that will return the

* actual speed of the monstetruck that

* is driven by the crazy clown IT .

*/

private void getSpeed()
```

Exercise 12 (important)

With which access-modification do you declare instance variables usually? Is it private or public? Do you have a reason for your answer?

Usually we declare instance variables as private. The reason for this is a common pattern that is used to get or set these data form outside the objects by so called accessor and mutator methods (getSpeed, setSpeed, changeSpeed).

Exercise 13

Explain the relation between a constructor and the state of an onject.

The constructor is creating (initializing) an object and has nothing to do with the state of the object once it's set up.

Exercise 14

How do we name constructors?

Constructors are usually named after the class their used for.

Exercise 15

What's the lifetyme of instance variables, how long are they reachable/accessable?

The lifetime of variables is coupled to the lifetime of their objects. As long as the object is alive the variables are also alive.

Exercise 16

Why sould you (if possible) initialise instance variables explicit?

If we don't initialize variables explicit the compiler will use default values for the initialization. By explicit initialisation we don't have any disadwantage and it serves well to document what is sctually happening.

Exercise 17

What's the defualt value which is given to a int variable by its initialisation?

The default value for an **int** is zero.

Exercise 19

What's the use of parameters?

Parameters provide additional information to a method or object. This is useful in many ways.

Exercise 20

What's the difference between a formal and a actual parameter?

A formal parameter is a parameter that is defined as parameter but has no actual value corresponding. A actual parameter is a parameter with a specific value.

Exercise 21

Is the following statement correct; "formal parameters are special variables"?

Parameters are temporary and restricted variables because their space is allocated by a call to the method or object and as soon as a value is transmitted to it. Once that call has completed its task, the formal parameter disappears and the values in it are lost.

Exercise 22

What's about the accessability of formal parameters?

The accessability of parameters are limited to the lifetime of the task which is creating them (method). Also parameter are only reachable from inside the box that they are used in (like a local variable).

Exercise 23

In which way this differs from instance variables?

Instance variables have a lifetime that is identical with the lifetime of their objects. Also parameters are only reachable from inside the block, instance variables are reachable from everywhere inside the class.

Exercise 24

How do the lifecycles of formal parameters and instance variables differ?

Instance variables are persistent (limited by lifetime of the object) and the lifetime of formal parameters is not really defined in runtime.

Programming and Algorithms

Exercise 26

How would you translate the expressions "assignment" and "expression" in german?

- assignment = Zuweisung
- expression = Ausdruck

Exercise 27

How does an assignment-instruction work exactly? What's about to be aware of in relation to data types?

An assignment can be done with the operator "=". For example:

```
// create a instance variable for speed
private int speed;

// set the speed
public void setSpeed(int newSpeed)
{
    speed = newSpeed;
}
```

By assigning data you have to be aware of data types. For example you can't assign a **int** to a **float** and so on. There are some strategies to "cast" or "parse" data between different data types but that's not our topic now.

2.4 Team Exercise 1-4

Create a Balloon-Class and create some objects and interact with them.

../workspace/balloon/src/flight/Balloon.java

```
package flight;
3
   * Balloon models a simple abstraction of a physical balloon.
4
  public class Balloon
      // size of the balloon. The balloon is abstracted a perfect
      // bowl defined by its diameter.
10
      private float diameter;
11
12
      // horizontal position of the balloon
13
      private int posHorizontal;
14
15
      // altitude (vertical position) of the balloon
16
      private int posVertical;
17
18
      // color of the balloon
19
      private String color;
20
      // number of the ballon
22
      private int number;
23
24
      // simple constructor
25
      public Balloon()
26
27
          diameter = 300f;
28
          posHorizontal = 300;
29
          posVertical = 300;
30
           color = "red";
31
32
33
      // more detailed constructor
34
      public Balloon(String newColor)
35
           color = newColor;
37
38
39
      public void setPosition(int newHorizontal, int newVertical)
40
41
           posHorizontal = newHorizontal;
42
           posVertical = newVertical;
43
      }
45
      public void setDiameter(float newDiameter)
46
47
           diameter = newDiameter;
48
49
50
```

```
public void setColor(String newColor)
51
52
           color = newColor;
53
54
55
       public void setNumber(int newNumber)
57
           number = newNumber;
58
59
60
       public int getHorizontal()
61
62
           return posHorizontal;
63
64
65
       public int getVertical()
66
67
           return posVertical;
68
69
70
       public float getDiameter()
71
           return diameter;
73
74
       public String getColor()
76
77
           return color;
78
79
80
       public int getNumber()
81
82
           return number;
83
84
85
```

../workspace/balloon/src/flight/Main.java

```
package flight;
 public class Main
      public static void main(String[] args)
          // create a new balloon (with the simple constructor)
          Balloon b1 = new Balloon();
          // get the current horizontal position
9
          System.out.println("Horizontal: " + b1.getHorizontal());
10
          // set a new horizontal position
11
          bl.setPosition(400, 400);
12
          // get the current horizontal position
13
          System.out.println("Horizontal: " + b1.getHorizontal());
14
15
          // create a new ballon with the detailed constructor
16
          Balloon b2 = new Balloon("yellow");
```

Programming and Algorithms

```
// get the color of the new ballon
System.out.println("Color: " + b2.getColor());;
}

20
}
21
```

2.5 Team Exercise 5

You want to write records, so you have to write a class Book for this. This class shall have the following four attributes:

- Title (String)
- Author (String)
- Price (float)
- Year on buy (int)

The class shall also have two constructors.

- Title and author are parameters. The books is not bought yet and this is why the price is 0.0 and the "year of buy" is -1.
- All attributes are initialized by parameters.

The class shall have the following methods.

- Two methods to get the title and author.
- A method to get and to set the year of buy.
- A method to get and to set the price.

../workspace/Book/src/library/Book.java

```
package library;
  public class Book
      // title of the book
      private String title;
6
      // author of the book
      private String author;
10
      // price of the book
11
      private float price;
12
13
      // year of buy
14
      private int year;
15
16
17
        * Create a new book with all attributes.
18
19
      public Book(String newTitle, String newAuthor, float newPrice, int
20
          newYear)
21
          title = newTitle;
          author = newAuthor;
23
          price = newPrice;
24
          year = newYear;
25
26
27
      public Book(String newTitle, String newAuthor)
28
```

```
29
           title = newTitle;
30
           author = newAuthor;
31
           price = 0.0f;
32
           year = -1;
33
       }
35
      public String getTitle()
36
37
           System.out.println("Title: " + title);
38
           return title;
39
       }
40
41
      public String getAuthor()
42
43
           System.out.println("Author: " + author);
44
           return author;
45
46
47
      public void setYear(int newYear)
48
49
           year = newYear;
50
51
52
      public void setPrice(float newPrice)
54
           price = newPrice;
55
       }
56
      public int getYear()
58
59
           System.out.println("Year: " + year);
60
61
           return year;
       }
62
63
      public float getPrice()
64
65
           System.out.println("Price: " + price + " USD");
66
           return price;
67
68
69
70
```

../workspace/Book/src/library/Main.java

Programming and Algorithms

```
bl.getYear();
bl.getPrice();

}

}
```

2.6 Team Exercise 5 - Optional

Think about banc accounts, their behaviour and attributes. Implement a class Account. To avoid round sum problems work with integer values. Play around with your class and get you some money!

../workspace/Account/src/money/Account.java

```
package money;
  public class Account
3
4
      private String ownerFirstName;
      private String ownerLastName;
      private String ownerAddress;
      private String ownerEMail;
      private int yearOfBirth;
      private int yearOfAccount;
10
      private int accountNumber;
11
      private long accountBalance;
12
      private long accountDebit;
13
      private long accountCredit;
14
      private boolean accountActive;
15
17
        * Create a new inactive account with default values.
18
       */
19
      public Account()
21
          ownerFirstName = "Default";
22
          ownerLastName = "Default";
23
          ownerAddress = "Default";
24
          ownerEMail = "Deafult";
25
          yearOfBirth = -1;
26
          yearOfAccount = -1;
27
          accountNumber = -1;
28
          accountBalance = 0;
29
          accountDebit = 0;
30
          accountCredit = 0;
31
          accountActive = false;
32
      }
33
34
        * Create a new active account.
36
       */
37
38
      public Account ( String newFirstName,
39
                        String newLastName,
40
                        String newAddress,
41
                        String newEMail,
42
                        int newYearOfBirth,
43
                        int newYearOfAccount,
44
                        int newAccountNumber,
45
                        long newAccountBalance)
46
47
           ownerFirstName = newFirstName;
48
          ownerLastName = newLastName;
49
```

```
ownerAddress = newAddress;
          ownerEMail = newEMail;
          yearOfBirth = newYearOfBirth;
52
          yearOfAccount = newYearOfAccount;
53
          accountNumber = newAccountNumber;
54
          accountBalance = newAccountBalance;
          accountDebit = 0;
56
          accountCredit = 0;
57
          accountActive = true;
58
59
60
      public String getOwnerFirstName()
61
62
          System.out.println("First name: " + ownerFirstName);
63
          return ownerFirstName;
64
65
      public void setOwnerFirstName(String newOwnerFirstName)
67
68
          ownerFirstName = newOwnerFirstName;
69
70
```

../workspace/Account/src/money/Main.java

```
package money;

public class Main
{
    public static void main(String[] args)
    {
        Account acc1 = new Account();
        acc1.getOwnerFirstName();
        acc1.setOwnerFirstName("David Barnes");
        acc1.getOwnerFirstName();
        acc1.getOwnerFirstName();
}
```

2.7 Selfstudy-Questions OOP3

Exercise 1

What is a header? What is a body?

A header is a part of a method. For example **public int** getSpeed() is the header of the method

```
public int getSpeed()
{
    return speed;
}
```

Exercise 2

Write down the signatures of the methods form class TicketMachine.

- getPrice(...)
- getBalance(...)
- insertMoney(int ...)
- printTicket(...)

Exercise 3

Where can you place expressions and definitions?

I don't understand that question.

Exercise 4

What is a block?

A block ist the part of a method which is between the curly braces.

Exercise 5

How many return expressions do you find in Code 2.1?

Exercise 7

What's the meaning of the return-type void?

The return type **void** indicates that the method has no return value.

Exercise 8

Fill out the table.

compound assignment	as	ssig	gni	ne	\mathbf{nt}
a += b	а	=	а	+	b
a -= b	а	=	а	_	b
a *= b	а	=	а	*	b
a /= b	а	=	а	/	b

Exercise 9

In the code of the TicketMachine, there are two places where you can place a compound assignment operator. Find those two places.

Exercise 12

Describe the conditional operator of the pseudo-code on page 42 in german. Try to translate the code in german (except for the keywords **if** and **else**.

Exercise 16

At pitfall on page 48 is a very important information. Translate the first sentence in german.

Exercise 17

Fill out the following table.

	Field	formal parameter	local variable
can store values?	Yes	No	limited
Where is/are they defined?	class	class	method
How long do they exist?	permanent	imaginary	limited
From where can you access them?	global	nowhere	localy

2.8 Team Exercise 1

```
2.5 * (2+3) = 12.5

(int) 2.5 * 2 + 3 = 7

(int) 2.5 * (2+3) = 10

(int) (2.5 * 2 + 3) = 8

(int) (2.5 * (2+3)) = 12

(int) 2.5 * 2 + (float) 3 = 7.0
```

2.9 Team Exercises 2

- What are konventions?

 Konventions are rules that are not strict.
- For whatr are they good for?

 They give the programmer a good orientation if every coder used the same conventions or if a coder used a convention consistantly. This improves the portability and make the code easy to maintain.
- Give the signatures for the following attributes by konventions:

```
String secondNamefloat hoursint personalNumberObject myObject
```

Answer

```
- public String getSecondName()
- public float getHours()
- public int getPersonalNumber()
- public Object getMyObject()
```

• Can you define a konvention for mutator-methods? Of course you can, just as for getter-methods.

2.10 Team Exercise 3

At the exercises 2.27 and 2.59 you had to note error messages.

- Compare your Notes
 "Missing return statement" and "unreachable statment".
- Try to define rules out of these error messages.

 If you use a return declaration in the header you have to use a return expression and the return expression has to be at the end of the block.

2.11 Team Exercise 4

Now you'll get into the **switch** expression on your own. You can use the appendix D of your book and the file Selection.jar from ILIAS

2.11.1 Team Exercise 4.1

Look at the following snippet.

```
public void output(int value)
2
      System.out.println();
      System.out.println("actual parameter: " + value);
      switch (value)

```
package choose;

public class Main

{
    public static void main(String[] args)
    {
        Selection mySel = new Selection();
        mySel.output(5);
        System.out.println("END OF PROGRAM");
    }
}
```

2.12 Summary exercises

3 Object interaction

3.1 Selfstudy-Questions OOP4

3.1.1 Chapter 3.6 - Class diagrams vs. object diagrams

Exercise 1

How do you declare a referencevariable?

A referencevariable is a variable that points to an object. For example Account myAccount = **new** Account(); defines a referencevariable myAccount. This variable doesn't contain a value but a reference to the storage-space where the object lays (like a pointer in C).

Exercise 2

Draw the object diagram to the BlueJ project "house" from chapter 1.

Exercise 3

Draw the class diagram to the BlueJ project "house" from chapter 1.

Exercise 4

Solve the exercises 3.1 to 3.4

3.1.2 Chapter 3.8 - The ClockDisplay source code

Exercise 1

Solve the exercise 3.5

Exercise 2

What is the result of the following expressions?

Question			Result
(3>2)	^	(4>5)	true
(3<2)	^	(4>5)	fasle
(3<2)	& &	(4>5)	false
(3>2)		(4>5)	true
! (3>2)			false

Exercise 3

Solve the exercises 3.6 to 3.8

- **3.6** Nothing happens. This implementation is not a good idea. To improve it we could use a error-message that is returned.
 - **3.7** We could not set the value to zero.
 - **3.8** If would be true for all inputs, because their either >0 or imit.

Exercise 4

Solve the exercises 3.15 to 3.17 and 3.19

```
\bf 3.15 The modulo operator returns the remainder of an division. \bf 3.16 8%3 returns 2 \bf 3.17 -10%3 returns -1, 10%-3 returns +1.
```

3.18 5-1 **3.19** m-1

Exercise 5

Solve the exercise 3.21

3.21

```
if((value+1) < limit) {
    value++;
}
else{
    value = 0;
}</pre>
```

3.1.3 Chapter 3.9 - Objects creating objects

Exercise 1

Solve the exercise 3.23

3.23 The time is "00:00". The constructor is responsible for this value.

3.1.4 Chapter 3.10 - Multiple constructors

Exercise 1

Create the singatures for all possible constructors which accord with the following object-creation. new Student("Peter", 34);

```
// simple creator with no parameters
  public Student()
3
      name = "No-Name";
      age = -1;
5
  }
6
  // creator with single-parameter name
  public Student(String newName)
9
10
      name = newName;
      age = -1
12
  }
13
  // creator with single-parameter age
```

```
public Student(int newAge)
17
      name = "No-Name";
18
      age = newAge;
19
20
21
  // creator with full paramterlist name, age
public Student (String newName, int newAge)
24
      name = newName;
25
      age = newAge;
26
27
```

Exercise 2

Solve the exercises 3.28 and 3.29

- 3.28 It creates two NumberDisplay objects with the overrolllimits 24 and 60.
- **3.29** Because it is set by the parameters given to the constructor.

3.1.5 Chapter 3.11 - Method calls

Exercise 1

Solve the exercise 3.30

3.30

```
// print the Payroll-Summary on Printer p1, two-sided
p1.print("Payroll-Summary.txt", true)

// print the Phone-List on Printer p1, single-sided
p1.print("Phone-List.txt", false)

// show the status of Printer p1 on the console
System.out.println(p1.getSatus(20))

// return the status of Printer p1
p1.getStatus(10)
```

3.1.6 Chapter 3.12 - Another example of object interaction

Exercise 1

Solve the exercises 3.33 and 3.34

3.33

../workspace/Mail-System/src/mails/Main.java

```
package mails;
public class Main
```

```
public static void main(String[] args)
6
          // create a MailServer
7
          MailServer MS1 = new MailServer();
          // create two MailClients
10
          MailClient MC1 = new MailClient(MS1, "Homer");
11
          MailClient MC2 = new MailClient(MS1, "Fry");
12
13
          // send a message from MC1 to MC2
14
          MC1.sendMailItem("Fry", "Hello Fry! How are you?");
15
16
          // show the mail at MC2
17
          MC2.printNextMailItem();
18
19
          // give an answer
20
          MC2.sendMailItem("Homer", "Hi Homer! I'm fine, thanks.");
21
22
          // show the mail at MC1
23
          MC1.printNextMailItem();

3.34

3.1.7 Chapter 3.13 - Using a debugger

Exercise 1

Solve the exercises 3.35 to 3.42

3.35 to 3.42

../workspace/Mail-System/src/mails/Sophie.java

```
package mails;
  public class Sophie
3
4
      public static void main(String[] args)
          // create a MailServer
          MailServer MS1 = new MailServer();
          // create two clients
10
          MailClient sophie = new MailClient(MS1, "Sophie");
11
          MailClient juan = new MailClient(MS1, "Juan");
12
          // send a message from sophie to juan
14
          sophie.sendMailItem("Juan", "Hello Juan. How are you?");
15
16
          // print the message at juans client
17
          juan.printNextMailItem();
18
19
          // check for new messages
20
          juan.printNextMailItem();
      }
22
  }
23
```

3.2 Team-Exercises

3.2.1 Exercise 1 - Using a debugger

Exercise 3.43, page 90

Exercise 3.44, page 90

3.2.2 Exercise 2 - Some random exercises

Exercise 3.9, page 71

Which of the following expressions return true?

Expression	Result
! (4<5)	true
!false	true
(2>2) ((4==4) && (1<0))	false
$(2>2) \mid \mid (4==4) \&\& (1<0)$	false
(34 != 33)&& ! false	true

Exercise 3.10, page 71

Write an expression using boolean variables a and b that evaluates to true when a and b are either true or both false.

! (a^b)

Exercise 3.11, page 71

Write an expression using boolean variables a and b that evaluates to true when only one of a and b is true, and that is false if a and b are both false or both true.

(a^b)

Exercise 3.12, page 71

Consider the following expression. Write an equivalent expression (one that evaluates true at exactly the same values for a and b) without using the AND Operator.

(a&&b)

3.2.3 Exercise 3 - Challanges

3.2.4 Exercise 4 - Programming (optional)

Exercise 3.45, page 91

Add a subject line for an e-mail to mail items in the mail-system project. Make sure printing messages also prints the subject line. Modify the mail client accordingly.

Exercise 3.46, page 91

Given the following class write some lines of java code that create a Screen object. Then call its clear method if (and only if) its number of pixels is greater than two million. (Don't worry about things being logical here; the goal is only to write something that is syntactically correct - i.e., that would compile if we typed it in.)

4 Grouping objects

4.1 Selfstudy-Questions OOP5

4.1.1 Chapter 4.1 to 4.3 - An organizer for music files

Exercise 1

Solve the exercises 4.1 to 4.3

4.1

../workspace/Music-Organiser-V1/src/music/MusicOrganizer.java

```
package music;
3
  import java.util.ArrayList;
   * A class to hold details of audio files.
6
   * @author David J. Barnes and Michael Kölling
   * @version 2011.07.31
9
  public class MusicOrganizer
11
12
      // An ArrayList for storing the file names of music files.
13
      private ArrayList<String> files;
14
15
16
       * Create a MusicOrganizer
17
18
      public MusicOrganizer()
19
20
           files = new ArrayList<String>();
21
22
23
      /**
24
       * Add a file to the collection.
25
        * @param filename The file to be added.
26
27
      public void addFile(String filename)
28
           files.add(filename);
30
31
32
33
       * Return the number of files in the collection.
34
       \star @return The number of files in the collection.
35
36
      public int getNumberOfFiles()
37
38
           return files.size();
39
40
41
42
       * List a file from the collection.
```

```
* @param index The index of the file to be listed.
44
        */
45
      public void listFile(int index)
46
47
           if(index >= 0 && index < files.size()) {</pre>
48
               String filename = files.get(index);
49
                System.out.println(filename);
50
           }
51
       }
52
53
54
        * Remove a file from the collection.
55
        * @param index The index of the file to be removed.
56
      public void removeFile(int index)
58
59
           if(index >= 0 && index < files.size()) {</pre>
60
                files.remove(index);
61
62
63
       }
64
  }
```

../work space/Music-Organiser-V1/src/music/Main.java

```
package music;
  public class Main
4
      public static void main(String[] args)
5
6
           // create a MusicOrganiser object
          MusicOrganizer myOrg = new MusicOrganizer();
9
           // store some tracks to it
10
          myOrg.addFile("Free Software Song");
11
          myOrg.addFile("Hacker after all");
12
          myOrg.addFile("CRE197 - IPV6");
13
14
          // check the number of tracks that are stored
15
          System.out.println("Number of Files: " +
16
                                myOrg.getNumberOfFiles());
17
18
          // show the name of the first, second and third track
19
          myOrg.listFile(0);
20
          myOrg.listFile(1);
21
          myOrg.listFile(2);
22
23
          // remove the first track and ask for the first track
24
          myOrg.removeFile(0);
25
          myOrg.listFile(0);
26
27
28
```

4.2 We don't get an error. As wee look at the code of the method we'll see, that the method is examinating if the index is "valid". If not it does not perform a remove action.

../work space/Music-Organiser-V1/src/music/MusicOrganizer.java

```
public void removeFile(int index)
{
    if(index >= 0 && index < files.size()) {
        files.remove(index);
    }
}</pre>
```

4.3 The list is shifted, so that the previously second track is the first track after removing the first track.

Exercise 2

What do you understand by "Java-Package"?

A Java-Package is just a collection of classes. It is a namespace to organize classes.

Exercise 3

You want to use the library-class ArrayList. What expression makes it possible to use that library-class in your source code?

```
If we want to use a library-class, we have to import it to our source with import java.nameOfTheLibraryClass;
```

```
So to use the ArrayList we just have to write in our source import java.util.ArrayList;
```

4.1.2 Chapter 4.4 to 4.7 - Numbering within collections

Exercise 4

Solve the exercises 4.4 to 4.7

Exercise 4.4, page 100

Write a declaration of a private field named library that can hold an ArrayList. The elements of the ArrayList are of type Book.

```
private ArrayList<Book> library = new ArrayList<String>();
```

Exercise 4.5, page 100

Write a declaration of a local variable called cs101 that can hold an ArrayList of Student.

```
private ArrayList<Student> cs101 = new ArrayList<Student>();
I'm not really sure about the "local" in the exercise. Do I have to specify that this is private or not?
```

Exercise 4.6, page 101

Write a declaration of a private field called tracks for sorting a collection of MusicTrack objects.

```
private ArrayList<MusicTrack> tracks = new ArrayList<MusicTrack>();
```

Exercise 4.7, page 101

Write assignments to the library, cs101 and track variables (which you defined in the previous three exercises) to create the appropriate ArrayList objects. Write them once without using diamond and once with diamond notation if you are using Java 7 compiler.

```
library.add("Objects First with Java");
cs101.add("Leonardo DaVinci");
track.add("Free Software Song");
```

I'm not really sure what is the question here ...

Exercise 5

Solve the exercises 4.8 to 4.11

Exercise 4.8, page 102

If a collection stores 10 objects, what value would be returned from a call to its size method?

It would return 9.

Exercise 4.9, page 102

Write a method call using get to return the fifth object stored in a collection called items.

```
items.get(4)
```

Exercise 4.10, page 102

What is the index of the last item stored in a collection of 15 objects?

This would be 14.

Exercise 4.11, page 102

Write a method call to add the object held in the variable favoriteTrack to a collection called files.

```
addFavorite(favoriteTrack, files)
I'm not really sure about this question ...
```

Exercise 6

Solve the exercises 4.12 to 4.13

Exercise 4.12, page 103

Write a method call to remove the third object stored in a collection called dates.

```
dates.remove(2)
```

Exercise 4.13, page 103

Suppose that an object is stored at index 6 in a collection. What will be its index immediately after the objects at index 0 and 9 are removed?

After removing index 0, the whole collection is shifted by -1, so the index of the element, which was at index 5 in the beginning would now be at 6-1=5. Removing an index after the queried one has non effect of the indexing, so it would still be 5.

Exercise 7

```
Explain the following declaration:
private ArrayList<Balloon> list = new ArrayList<>();
```

A private collection (ArrayList) of type Balloon is set up.

Exercise 8

What is the connection between abstraction and ArrayLists?

Abstraction has the goal to simplify as far as possible. The class ArrayList provides great funcionalities that are helping to use the conecept of abstraction by minimizing effort in programming a complex class but using a library-class (ArrayList) which is giving a lot of useful and powerful methods. In other words, if we want to manage a collection, we don't want to use our time to implement complex code to manage our collection, we just want to specify how we want to manage. So we use preexisting code (from a library-class like java.util.ArrayList).

Exercise 9

What is the difference of the methods remove() and get() on ArrayLists?

The remove () method of ArrayList is removing the specified objects out of the collection. This is causing a reindexation of all items of the collection that have a higher index as the removed once. These following items will get a new index which is "actual index - 1".

The get () method of ArrayList is returning the element at the specified index. The element is in general a object but it could also be a simple type.

4.1.3 Chapter 4.8 to 4.12 - The Iterator type

Exercise 10

Solve the exercises 4.18 to 4.19

Exercise 4.18, page 106

What might the header of a listAllFiles method in the MusicOrganizer class look like? What sort of return type should it have? Does it need to take any parameters

The header of such a method would certainly not have a parameter and probably the return type void since it would use System.out.println() so the header could look like

```
public void listAllFiles()
```

Exercise 4.19, page 106

We know that the first file name is stored at index zero in the ArrayList and the list stores the file names as strings, so could we write the body of listAllFiles along with the following lines?

```
System.out.println(files.get(0));
System.out.println(files.get(1));
System.out.println(files.get(2));
```

We could do so if we would be sure that there won't be more than three used indexes or three tracks. If we would like to have an arbitrary number of tracks we should use a other body, for instance with a loop.

A easy and intended loop for this job is a so called *for-each loop*. The course book is suggesting the following code.

```
public void listAllFiles()
{
    for(String filename : files)
    {
        System.out.println(filename);
    }
}
```

Exercise 11

Solve the exercise 4.22

Just something to play in BlueJ (creating an ArrayList and add, remove, ..., some objects to it).

Exercise 12

Explain as detailed as possible the source code on page 108.

```
public void listAllFiles()
{
    for(String filename : files)
    {
        System.out.println(filename);
    }
}
```

In the first line we see the header of the method. It is declaring that the method is of type public, that it has no return type (void) and does not take any parameters.

In the third line we see the header of the so called for-each loop. This means translated "for each element of the ArrayList files, do the following body". Since the ArrayList files is containing Strings, we need to declare "element" as String. So for every round thru the loop, the incremented index of the element that it contains at this index is stored to the local variable "element" that we defined to be of type String.

In the fifth line of code we see the print method, which is printing the "element" to the console, so it prints the String that is at the actual index of the loop.

Is it possible, that the body of an while-loop is never executed?

Yes of course it is possible because there is a condition that is deciding if the body is run or not.

Exercise 14

Show two alternative expressions for no++

```
n += n;
n = n + n;
```

Exercise 15

An ArrayList can be traversed by an foreach-loop. Do you know other ways to do the same?

Yes, there is a so called Iterator.

Exercise 16

Is hasNext() a method of ArrayList or Iterator? How do you have to understand/interpret the return-value of hasNext()?

hasNext () is a method of Iterator. This method returns a **true** if there is a element in the collection after the current one and **false** if not.

4.1.4 Chapter 4.14 - Summary of the music-organizer project

Exercise 17

DO NOT READ THIS CHAPTER, JUST READ THE CONCEPT-BOX AT PAGE 130.

Exercise 18

A variable that is declared for a classtype (or so called reference-variable) can store the special value null. Explain the situation with a drawing/sketch. What does it look like, if it's storing an object?

The following sketch 1 shows a comparison of two variables of type Balloon. One is just declared with Balloon a; and the other is initialized with Balloon b = new Balloon();

The difference is that b is showing or pointing to the object in the memory and since a has no object to show to is has a pointer to **null**.

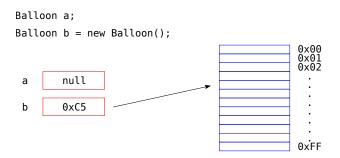

Figure 1: A declared and initialized object in comparison.

4.1.5 Chapter 4.15 to 4.17 - Summary

Exercise 19

```
Solve the exercises 4.62 to 4.65

4.62 Person[] people;
4.63 boolean[] vacant;
4.64 ???

4.65 The declaration is wrong (syntax). It should look like int[] counts;
boolean[] occupied = new boolean[5000];
```

Exercise 20

Solve the exercises 4.66 to 4.68

4.66

```
double[] readings;
String[] urls;
TicketMachine[] machines;

readings = new double[6];
urls = new String[90];
machines = new TicketMachine[5];
```

4.67 With String[] labels = **new** String[20] 20 String objects are created.

4.68 The correct expression is **double**[] piece = **new double**[50];

Exercise 21

What are the pros and cons of Arrays?

- ✓ Arrays are more efficient in access.
- ✓ Arrays can store primitive-types as well as objects.
- **X** Arrays have a fixed size.

Exercise 22

How do you get the length of an Array?

The length of an array is accessable by the length operator.

```
// create an array of type int with the length 50
int[] i = new int[50];

// return the length of the array
public int getLength(int[] array)
{
    return array.length;
}
```

Solve the exercises 4.69, 4.71, 4.73 and 4.74

 $\bf 4.69$ This will fail in an error called $\it Out\ Of\ Bound\ Execption.$ $\bf 4.71$

4.73

```
public int numberOfAccesses()

int total = 0;

for(ctr = 0; ctr < hourCounts.length; ctr++)

total += hourCounts[ctr];

return total;

}</pre>
```

4.74

5 More-sophisticated behavior

5.1 Selfstudy-Questions OOP6

5.1.1 Chapter 5.2 - The TechSupport system

Exercise 1

Solve the exercise 5.1

../workspace/TechSupport/src/support/Main.java

```
package support;

public class Main
{
    public static void main(String[] args)
    {
        // create a support system and start it
        SupportSystem sys = new SupportSystem();
        sys.start();
}
```

Exercise 2

At page 157 and 158 there is a Method start() that uses a while-loop. Create a code snippet with the same functionality by using a do-while loop.

```
public void start()
2
      boolean finished = false;
      printWelcome();
      do{
          String input = reader.getInput();
          if(input.startsWith("bye")){
               finished = true;
10
          } else{
11
               String response = responder.generateResponse();
12
               System.out.println(response);
13
14
      }while(!finished)
15
16
      printGoodbye();
```

5.1.2 Chapter 5.3 - Reading class documentation

Exercise 3

Solve the exercises 5.2 to 5.5 as well as 5.7 to 5.11

5.2 The Java documentation has a clear design. Every class like String is described in different sections, to get as fast as possible to the information needed. This documentation is arranged by the following sections:

- Summary
 - Nested
 - Field
 - Constructor
 - Method
- Detail
 - Field
 - Constructor
 - Method
- **5.3** The class String has two methods called startsWith, where one method has only one parameter (String) and the other has two parameters (String and int). The method that has only one parameter is returning **true** if the specified string is found at the very beginning of the specified String object. The other method with two parameters is returning **true** if the specified string is found after the specified offset. The offest is a int value representing the number of characters.

Here is an example for the behavior. Both of these if statements are returning true.

```
String s = "Hi, my name is Avaj Elcaro.";

// check if the very beginning of the String object is "Hi"

if(s.startsWith("Hi")) {
    System.out.println("found match at the very beginning");
}

// check if the String object has the string "my" after the 4th character

if(s.startsWith("my", 4)) {
    System.out.println("found match after the 4th character");
```

5.4 There is a method in the class String that checks if a String ends with a specified suffix.

```
public boolean endsWith(String suffix)
```

5.5 There is a method in the class String that returns the number of unicode characters in a specified string.

```
public int length()
```

In which package do you suppose the class File Writer? Check your guess with the Java API documentation.

The class FileWriter is a part of the package java.io where the io stands for Input-Output.

Exercise 5

With the class BufferReader you can read files line by line. How does that work? You can find the answer in the Java API documentation.

We can use the method readLine() for that job. Here is an example form http://www.roseindia.net/java/beginners/java-read-file-line-by-line.shtml

```
import java.io.*;
  class FileRead
      public static void main(String args[])
          try{
6
               // Open the file
              FileInputStream fstream = new FileInputStream("textfile.txt");
               // Get the object of DataInputStream
              DataInputStream in = new DataInputStream(fstream);
10
              BufferedReader br = new BufferedReader(new
11
                  InputStreamReader(in));
               String strLine;
12
               //Read File Line By Line
13
              while ((strLine = br.readLine()) != null)
14
                   // Print the content on the console
15
                   System.out.println (strLine);
16
               }
17
               //Close the input stream
18
               in.close();
          }catch (Exception e) {//Catch exception if any
20
               System.err.println("Error: " + e.getMessage());
21
22
          }
23
      }
```

5.1.3 Chapter 5.4 - Adding random behavior

Exercise 6

Solve the exercises 5.12 and 5.13

5.12 The Random class is from the package java.util. It is used to generate a stream of pseudorandom numbers. An instance can be constructed with the following code.

```
import java.util.Random;
public class Main
{
```

```
public static void main(String[] args)

{
    // create an instance of Random
    Random rand = new Random();

// print out 10 random numbers between 0 and 20

for(int i = 0; i < 10; i++)

{
    System.out.println(rand.nextInt(21));
}
</pre>
```

5.13 See 5.12

Solve the exercise 5.15

If we use rand.nextInt (100) we will get any integer number between 0 and 99.

Exercise 8

Solve the exercise 5.18

Simple example of a random response program.

../work space/Snippets/src/random Response/Random Response.java

```
package randomResponse;
  import java.util.ArrayList;
  import java.util.Random;
 public class RandomResponse
7
      public static void main(String[] args)
          // create an ArrayList for String objects
10
          ArrayList<String> responses = new ArrayList<String>();
12
          // create an Random instance
13
          Random rand = new Random();
14
          int ans = 0;
16
          // add some responses to the ArrayList
17
          responses.add("Have you tried turning it off and on again?");
18
          responses.add("Are you sure you have the latest update installed?");
          responses.add("Maybe you should upgrade to platinum version.");
20
          responses.add("Have you tried a complete new setup?");
21
          responses.add("I'm on pause now, I'll be back in 5 minutes.");
22
          responses.add("I'm new to this company and I didn't see such a
             problem yet.");
24
          // give a random responses
25
          System.out.println(responses.get(rand.nextInt(responses.size())));
```

Programming and Algorithms

```
27 }
28 }
```

5.1.4 Chapter 5.5 - Packages and import

Exercise 9

Solve the exercises 5.21 and 5.22

5.21 See Exercise 8 - 5.18

5.22 If we implement the response generation like in the example code above, it will work for any number of responses in the ArrayList. This is because the code is flexible for the size of the ArrayList.

5.2 Selfstudy-Questions ALG1

Exercise 10

Describe in words or as pseudocode one algorithm per problem.

(a) Calculate the product of two integers without a multiplication-operator.

One possible approach to solve this problem could be to use simple addition and iteration. This is because a multiplication, for example $3 \cdot 5 = 15$, can be substituted with (3 + 3 + 3 + 3 + 3) = (5 + 5 + 5) = 15.

../workspace/Snippets/src/multiply/Multiplier.java

```
package multiply;
2
 public class Multiplier
3
      public Multiplier()
6
      public int multiply(int a, int b)
10
11
            int result = 0;
12
            if((a==0) || (b==0)){
13
                 return 0;
14
            } else if(a < b) {</pre>
15
                 for(int i = 0; i < b; i++) {</pre>
16
                      result += a;
17
                 }
18
            } else{
19
                 for(int i = 0; i < a; i++) {</pre>
20
                      result += b;
21
22
23
            return result;
       }
25
26 }
```

../workspace/Snippets/src/multiply/Main.java

```
package multiply;

import java.util.Random;

public class Main
{
    public static void main(String[] args)
    {
        int product = 0;
        int factor1 = 0;
        int factor2 = 0;
}
```

```
// create a Random instance
13
          Random rand = new Random();
14
          Multiplier multi = new Multiplier();
15
16
17
          // do a multiplication
          factor1 = rand.nextInt(10);
19
          factor2 = rand.nextInt(10);
20
          product = multi.multiply(factor1, factor2);
21
          System.out.println(factor1 + " times " + factor2 + " = " +
22
              product);
23
24
```

An alternative approach is to think of the factors as binary numbers. In the binary system we multiply also by a addition. See the following example: Lets multiply $11 \cdot 14 = 154$. In binary this looks like following:

If we wanted to implement that alorithm, we would have to operate binary, but in fact that would be not really different form the fist approach.

(b) Find the lowest number out of a sequence like S = 4, -1, 50, 10, 0, 1, -2, 5, 10

../workspace/Snippets/src/search/Main.java

```
package search;
  import java.util.Random;
 public class Main
6
      public static void main(String[] args)
           // create a random sequence
           Random rand = new Random();
10
           int size = 10;
11
           int range = 100;
12
           int[] seq = new int[size];
13
           String sequence = "Sequence: ";
14
           for(int i = 0; i < size; i++) {</pre>
15
               seq[i] = rand.nextInt(range) - (range/2);
16
               sequence += seq[i] + ", ";
17
           }
18
19
           // show the sequence
20
           System.out.println(sequence);
21
22
```

```
// get the biggest value
23
           System.out.println("Biggest value in sequence: " +
24
               getBiggest(seq));
25
           // get smallest value
26
           System.out.println("Smallest value in sequence:" +
27
               getSmallest(seq));
      }
28
29
      public static int getBiggest(int[] sequence)
30
31
           int biggest = sequence[0];
32
           for(int i = 0; i < sequence.length; i++) {</pre>
33
                if (sequence[i] > biggest) {
                    biggest = sequence[i];
35
36
37
           return biggest;
38
39
40
      public static int getSmallest(int[] sequence)
41
           int smallest = sequence[0];
43
           for(int i = 0; i < sequence.length; i++) {</pre>
44
                if (sequence[i] < smallest) {</pre>
45
                    smallest = sequence[i];
46
47
48
           return smallest;
49
50
51
```

Implement an algorithm to calculate the greatest common divisor with the modulo operator (see ALG1 presentation, page 12).

../workspace/Snippets/src/euklid/Main.java

```
package euklid;
  import java.util.Random;
  public class Main
6
      public static void main(String[] args)
          // create two random numbers
          Random rand = new Random();
10
          int range = 20;
11
          int num1 = rand.nextInt(range) + 1;
12
          int num2 = rand.nextInt(range) + 1;
13
14
          // get the greatest common divisor
15
```

```
System.out.println( "GCD of "
16
                                    + num1
17
                                    + " and "
18
                                    + num2
19
                                    + " is "
20
                                    + gcd(num1, num2));
21
22
23
       public static int gcd(int a, int b)
24
            while((a != 0) && (b != 0)){
26
                if(a > b) {
27
                     a = a % b;
28
                else{
30
                     b = b % a;
31
32
33
            return (a + b);
34
35
36
  }
```

- (a) Test your algorithm with some examples.
- (b) Change your algorithm so that you don't use the modulo operator. Change the modulo operation with a combined expression and test your implementation again.

Hint: The modulo operator can be substuituted by a sequence of subtractions that is finished as the result is smaller than the subtrahend.

../workspace/Snippets/src/euklid2/Main.java

```
package euklid2;
2
 import java.util.Random;
 public class Main
5
  {
6
      public static void main(String[] args)
8
           // create two random numbers
9
          Random rand = new Random();
10
          int range = 20;
11
          int num1 = rand.nextInt(range) + 1;
12
          int num2 = rand.nextInt(range) + 1;
13
          // get the greatest common divisor
15
          System.out.println( "GCD of "
16
                                + num1
17
                                + " and "
18
                                + num2
19
                                 + " is "
20
                                 + gcd(num1, num2));
21
22
23
      public static int gcd(int a, int b)
24
```

```
25
            // the arguments must not be 0
26
            if((a == 0) || (b == 0)){
27
                 return 0;
28
29
            while(a != b){
30
                 if(a > b){
31
                      a = a-b;
32
                 } else{
33
34
                      b = b-a;
35
36
            return a;
37
38
39
```

What's the order of the algorithm to calculate the n-th pseudo random number z (see OOP6 presentation page 28 and ALG1 presentation page 15)?

```
z_{n+1} = (a \cdot Z_n + r)\%m
```

5.3 Programming Exercise

Write a class FormLetter that is able to produce serial letters. The class has an ArrayList of type FormalAddress (see OOP3). With the method addAddress() a new object of type FormalAddress is generated and added to the ArrayList. With the method void print(int actualYear, String subject, String textBody) a new serial letter is generated for all elements in the ArrayList. The letter contains a greeting, a subject and of cource the text itself. This shall be printed to the console.

../workspace/FormLetter/src/letter/Main.java

```
package letter;
 public class Main
3
4
      public static void main(String[] args)
          FormLetter myLetter = new FormLetter();
          myLetter.addAddress("Richard", "Stallman", "Freeroad 91",
              "Freetown");
          myLetter.addAddress("Linus", "Torvalds", "Unixstreet 101",
10
              "Helsinki");
          myLetter.addAddress("Ervin", "Knuth", "Stanfordstreet 5",
11
              "Brooklyn");
12
          myLetter.print(2013, "New Kernel Realease",
13
                   "I'd like to inform you that there is a new Kernel
                      release.");
15
16
```

../work space/Form Letter/src/letter/Form Letter.java

```
package letter;
  import java.util.ArrayList;
  public class FormLetter
6
      private ArrayList<FormalAddress> fa = new ArrayList<>();
      public FormLetter() {
9
10
11
12
      public void addAddress (String firstname,
13
                               String lastname,
14
                               String address,
15
                               String city)
17
          FormalAddress newAdress = new FormalAddress(firstname,
18
                                                         lastname,
19
                                                         address,
20
                                                         city);
21
          fa.add(newAdress);
22
23
      }
24
      void print(int actualYear, String subject, String textBody)
25
26
          for (FormalAddress a : fa) {
27
              System.out.println("=======");
              System.out.println(a.getName());
29
              System.out.println(a.getAddress());
30
              System.out.println(a.getCity());
              System.out.println("");
32
              System.out.println(subject);
33
              System.out.println("");
34
              System.out.println("Dear" + a.getName() + ",");
35
              System.out.println(textBody);
36
              System.out.println("");
37
              System.out.println("=======");
38
          }
39
40
      }
41
42
```

../workspace/FormLetter/src/letter/FormalAddress.java

```
package letter;

public class FormalAddress
{
    private String firstname = "Default";
    private String lastname = "Default";
    private String address = "Default";
    private String address = "Default";
    private String city = "Default";
```

```
public FormalAddress(
                                  String newFirstName,
10
                                  String newLastName,
                                  String newAddress,
12
                                  String newCity)
13
           firstname = newFirstName;
15
           lastname = newLastName;
16
           address = newAddress;
17
18
           city = newCity;
19
20
      public String getName() {
21
           return firstname + " " + lastname;
23
24
      public String getAddress() {
25
           return address;
26
27
28
      public String getCity() {
29
           return city;
30
31
32
```

5.4 Team-Exercise

5.4.1 Exercise 1

Create a class ListIteratorApplication with the attribute of type ArrayList for Strings. Fill the ArrayList with the words of the sentence "With the iterator it is possible to tavers Lists back and forth".

- 1. Program a method iterateDown() that is iterating through the ArrayList. Use a Iterator for this method.
- 2. Program a method iterateUp() that is iterating reverse through the ArrayList. Use a for-loop and the get() method form ArrayList.
- 3. Program a method iterateBothWays() that is iterating through the ArrayList and then backwards. Use the ListIterator for this method and take a look at the API documentation of it.
- 4. Optional Ecerxice: Use the StringTokenizer to fill the ArrayList. An example is given by the OOP5 presentation on page 10. Take also a look at the API documentation.

../workspace/ListApp/src/list/Main.java

```
lia.iterateDown();
lia.iterateUp();
lia.iterateBothWays();
}
```

.../workspace/ListApp/src/list/ListIteratorApplication.java

```
package list;
  import java.util.ArrayList;
  import java.util.Iterator;
  import java.util.ListIterator;
  import java.util.StringTokenizer;
  public class ListIteratorApplication
      ArrayList<String> sentence = new ArrayList<String>();
10
11
      public ListIteratorApplication(String input)
12
13
          snipString(input);
14
15
          /\star this would be needed without the snipString() method
16
          sentence.add("With");
          sentence.add("the");
18
          sentence.add("ListIterator");
19
          sentence.add("it");
20
          sentence.add("is");
21
          sentence.add("possible");
22
          sentence.add("to");
23
          sentence.add("travers");
          sentence.add("Lists");
25
          sentence.add("back");
26
          sentence.add("and");
27
          sentence.add("forth");
28
          */
29
30
31
      public void iterateDown() {
          Iterator<String> it = sentence.iterator();
33
          while(it.hasNext()){
34
               System.out.print(it.next() + " ");
35
36
          System.out.println("");
37
38
39
      public void iterateUp() {
40
          Iterator<String> it = sentence.iterator();
41
          for(int i = sentence.size(); i > 0; i--){
42
               System.out.print(sentence.get(i-1) + " ");
43
44
          System.out.println("");
45
46
```

```
47
      public void iterateBothWays() {
48
           ListIterator<String> it = sentence.listIterator();
49
           while(it.hasNext()){
50
               System.out.print(it.next() + " ");
51
52
           System.out.println("");
53
54
           while(it.hasPrevious()){
55
               System.out.print(it.previous() + " ");
56
57
           System.out.println("");
58
59
      public void snipString(String input) {
61
           StringTokenizer st = new StringTokenizer(input);
62
           while(st.hasMoreElements()){
               sentence.add(st.nextToken());
64
65
66
      }
67
  }
```

5.4.2 Exercise 2

A sequence of integers is arranged in an array. A subsequence of a sequence is of arbitrary length but is combined by trailed parts of it. See the following example.

```
int[] series = {5, -8, 3, 4, -5, 7, -2, -7, 3, 5}
int[] subseries1 = {5, -8, 3}
int[] subseries2 = {-5, 7, -2, -7, 3}
```

Of course an empty sequence is also a valid subsequence. A subtotal is the sum of all entries of a subsequence. The subtotal of subseries1 form the example is 0, the subtotal of subseries2 is -4. An empty subsequence has the subtotal 0. The following pseudocode describes a intuitiv algorithm.

```
For all start values form 0 up to the length of the sequence
For all end values from start value up to the length of the sequence
Calculate the sum of the subsequence form start value up to the end
value
Is it the maximum sum?
```

- 1. What order has the algorithm described above?
- 2. Create a method public int maxSubtotal(int[] sequence) in class Series, which implements the algorithm above.
- 3. Test your implementation with a testmethod, which generates different sequences and calls the method maxSubtotal().

5.5 Selfstudy-Questions OOP7

5.5.1 Chapter 5.6 - Using maps for associations

Exercise 1

Solve the exercises 5.24 to 5.30

- **5.24** HashMap is a parameterized class and these are the mehtods that depend on the type.
- 5.25 If we want to know how many entries are contained in a map we can use the size() method.
- **5.26** A very simple phone book implementation with HashMap.

../workspace/Snippets/src/phoneBook/Main.java

```
package phoneBook;
3
 public class Main
      public static void main(String[] args)
          // create a new phoneBook
          MapTester myContacts = new MapTester();
          // add some entries
          myContacts.enterNumber("Richard Stallman", "1234567890");
11
          myContacts.enterNumber("Donald Ervin Knuth", "1123581321");
12
13
          // lookup for the numbers
          System.out.println(myContacts.lookupNumber("Richard Stallman"));
15
          System.out.println(myContacts.lookupNumber("Donald Ervin Knuth"));
16
          if (myContacts.checkForKey("Richard Stallman")) {
18
              System.out.println("Yep, he's in your phonebook!");
19
          } else{
20
              System.out.println("Nope, he's not in your phonebook!");
21
      }
23
24
```

../work space/Snippets/src/phone Book/Map Tester. java

```
package phoneBook;
import java.util.HashMap;

public class MapTester
{
    private HashMap<String, String> myMap = new HashMap<String, String>();

public MapTester()
{
    public void enterNumber(String name, String number)
}
```

```
myMap.put(name, number);
16
      }
17
18
      public String lookupNumber(String name)
19
20
           return myMap.get(name);
21
22
23
      public boolean checkForKey(String key)
24
           return myMap.containsKey(key);
26
27
28
  }
```

5.27 If a map is holding a key and a new pair is added with the same key, the previous value is overwritten by the new value. See the following example.

```
// add a pair for the key "A" with value "a"
myMap.put("A", "a");

// add a pair for the key "A" with value "b"
myMap.put("A", "b");

// lookup the value for the key "A"
System.out.println(myMap.get("A"))
```

The output will be "b" and there is only one pair for the key "A".

5.28 If you put two different keys to a map there will be two keys in this map. That's it, it is the usual usage.

5.29 If I want to know if there is already a key stored contained in a map I have to use the containsKey(Object key) method.

```
// add a pair for the key "A" with value "a"
  myMap.put("A", "a");
  // add a pair for the key "A" with value "b"
  myMap.put("A", "b");
5
  // check for the key "A"
  if (myMap.contains("A")) {
      System.out.println("Key is already there!");
9
  }
10
11
  else{
      System.out.println("Key isn't set yet!");
^{12}
13 }
```

5.30 I don't get the question.

Exercise 2

For what kind of lookups are maps the ideal collections? Maps are ideal for paired information like a phonebook or similar.

5.5.2 Chapter 5.8 - Dividing Strings

Exercise 3

Solve the exercises 5.35 and 5.37

5.35 The method split () is used to separate a string into different strings. The method is taking one parameter which is defining the separator. See the following example.

```
String myString = "Hello. My Name is Foo. I live in Bar."

String[] mySubStrings = myString.split(".");
```

This example above will create a new array of String with size 2 and the strings "Hello", "My Name is Foo", "I live in Bar".

5.36 If you want to split a string at ":" then give that as parameter to the split method.

5.37 If you split a string in pieces and return them to an HashSet, then you will have every string only once in that HashSet. If you return it to an ArrayList you'll get the whole string there and it's indexed, so you can only search by iteration.

5.5.3 Chapter 5.10 - Writing class documentation

Exercise 4

Solve the exercises 5.46 to 5.48

5.46 To generate documentation for Java code you can use the command line tool javadoc. If we want to document a single file (class), we can run the following command

```
$ cd /path/to/source
$ javadoc -d myDocumentation File.java
```

This command will make a new directory named myDocumentation and there it places a bunch of HTML files including the documentation for the given file. If you want to document all Java files in that directory, you can change the command to

```
$ javadoc -d myDocumentation *.java
```

5.47 Some javodoc key symbols from the TechSupport project are

- @author
- @version
- @return

Not all of these key symbols do influence the formatting of the documentation but @return does (see the documentation for details).

5.48 There is a nice table for all tags (key symbols) on wikipedia, see http://de.wikipedia.org/w/index.php?title=Javadoc&oldid=124140284

Comment one of your own projects with javadoc.

../workspace/Snippets/src/recursions/Main.java

```
package recursions;
3
  * This is a test project to write a recursive method.
4
   * @author ninux
  * @version 1.0
8 public class Main
      /**
10
       * The main method is defining a fixed array of type integer
11
       * with the values \{1,2,3,4,5\}. This array will be printed
12
       * reverse with the method reverse
13
       * @param args
14
       */
15
      public static void main(String[] args)
16
          int[] myRow = new int[]{1,2,3,4,5};
18
          reverse(myRow, (myRow.length-1));
19
20
      }
21
22
       \star This method is taking an array and prints it in reverse order.
23
       \star The index specifies the first element of the array that shall
24
       \star be printed. The common value for the index is (array.length - 1).
25
       * @param array
26
       * @param index
27
       */
28
      public static void reverse(int[] array, int index){
29
          System.out.println(array[index]);
30
          if(index > 0){
31
               reverse (array, index-1);
32
33
      }
34
35
  }
```

5.5.4 Chapter 5.13 - Class variables and constants

Exercise 6

Solve the exercise 5.68

• A public variable that is used to measure tolerance, with the value 0.001.

```
public static final double TOLERANCE = 0.001;
```

• A private variable that is used to indicate a pass mark, with the integer value of 40.

```
private static final int PASSMARK = 40;
```

• A public character variable that is used to indicate that the help command is 'h'.

```
public static final char HELP = 'h';
```

5.6 Selfstudy-Questions ALG1

Exercise 7

The following method shall be called with a actual parameter. Durign the execution the maximum height of the call-stack is 5. So how many times was the method coolMethod() called?

```
public int coolMethod(int n)
{
    if(n >= 2) {
        return (coolMethod(n-1) + coolMethod(n-2));
    }
    else{
        return n;
    }
}
```

Figure 2: Graphical explanation of call stack rising.

Implement a recursive algorithm for the calculation of the faculty (see presentation ALG2, page 9). Debug you method for the faculty of 4.

../workspace/Snippets/src/faculty/Main.java

```
package faculty;
  public class Main
      public static void main(String[] args)
           System.out.println(fac(6));
9
      public static int fac(int n)
10
11
           if(n <=1){
12
               return 1;
13
           }
14
           else{
15
               return (n*fac(n-1));
16
17
       }
18
  }
19
```

Exercise 9

Implement a recursive method to print an array forwards and backwards (see presentation ALG2, pages 29 and 30).

../workspace/Snippets/src/reverse/Main.java

```
package reverse;
 public class Main
      public static void main(String[] args)
          int[] myArray = new int[]{0,1,2,3,4,5,6,7,8,9};
          printBackAndForth(myArray, myArray.length, 0);
10
      public static void printBackAndForth(int[] array, int length, int index)
11
12
          System.out.println("Forward: ");
13
          printForth(array, length, index);
14
          System.out.println("\nBackwards: ");
15
          printBack(array, length, index);
16
17
      public static void printForth(int[] array, int lenght, int index)
19
20
```

```
System.out.print(array[index] + ", ");
21
22
           if(index < (lenght-1)){</pre>
23
                printForth(array, lenght, index+1);
24
25
      }
26
27
      public static void printBack(int[] array, int length, int index)
28
29
           if(index == array.length) {
30
                return;
31
           }
32
           else{
33
                printBack(array, length, index+1);
                System.out.print(array[index] + ", ");
35
           }
36
       }
37
38
```

Implement a recursive method that is calculating the sum of all integer values of an array. Make a documentation with javadoc.

../workspace/Snippets/src/sum/Main.java

```
package sum;
  public class Main
3
      public static void main(String[] args)
          int[] myArray = new int[]{0,1,2,3,4,5,6,7,8,9};
           System.out.println(sum(myArray, myArray.length, 0));
9
10
      public static int sum(int[] array, int length, int index)
11
12
13
          if(index < (length-1)){</pre>
14
               return array[index] + sum(array, length, index+1);
16
          else{
17
               return array[index];
18
           }
      }
20
```

Additional Exercise

Think about a algorithm that can perform a permutation on an array. Lets say for the sequence 1,2,3,4.

The idea is that we have to use a tree. The tree shows every possible path that can be used for the rearrangement of the numbers. If we start with the number 1, what are the possible paths that we can

go trough? See the graphical tree in picture 3 to get an idea of it.

Figure 3: Tree for permutation of 1,2,3,4 beginning with 1.

So we see, that the tricky part is at the end because the last two segments are turned around while the other are just incremented.

5.7 Team-Exercise

5.7.1 Exercise 1

Solve the exercise 5.71

../workspace/StarWars/src/star/NameGenerator.java

```
package star;
  public class NameGenerator
      public NameGenerator()
9
10
11
       * This method returns a name that is created by the
12
        * Star Wars algorithm.
13
        * @param yourLastName
14
        * @param yourFirstName
15
        * @param yourMothersMaidenName
16
       * @param yourHomeTownName
17
       * @return
18
      public String generateStarWarsName (String yourLastName,
20
                                             String yourFirstName,
21
                                             String yourMothersMaidenName,
22
                                             String yourHomeTownName)
24
          String newFirstName;
25
          String newLastName;
26
```

```
/**
28
            * The new first name is built by the first three letters
29
            * of the last name and the first two letters of the
30
            * first name.
31
32
          newFirstName = yourLastName.substring(0,3) +
                   yourFirstName.substring(0,2);
34
35
           /**
36
            * The new last name is built by the first two letters of
37
            * the mothers maiden name and the first three letters of
38
           * the home town.
39
40
          newLastName = yourMothersMaidenName.substring(0, 2) +
                   yourHomeTownName.substring(0,3);
42
43
          /**
44
            * Return the new names as full name (first and last name)
45
            * separated by a whitespace.
46
47
          return newFirstName + " " + newLastName;
48
49
50
51
```

../workspace/StarWars/src/star/Main.java

```
package star;

public class Main
{
    public static void main(String[] args)
    {
        NameGenerator ng = new NameGenerator();
        System.out.println(ng.generateStarWarsName("Nino", "Ninux", "Fooman", "Bartown"));
    }
}
```

Glossary

\mathbf{A}

abstraction

Abstraction describes the ability to ignore details and focus attention on a higher level of a problem. As an example think about an car as a Parking-Boy. You would ignore how many seats the cas has, but not how big it is, because it's relevant for your task.. 64

access modifier

A access modifier defines the visibility of the declared field, constructor or method. There are only four of them in Java: **private** (visible only from inside the same class), nothing specified aka. default (visible inside the same package), **protected** (visible form inside the same package and subclasses) and **public** (visible from everywhere). 64, 65

accessor

A accessor or accessor method is a method that provides access to information about an object's state (get-methods). 64

array

An array is a special type of collection that can store a fixed number of items. These items have to be of the same data type. 64

assignment

An assignment (statement) is a directive to assign a value into a variable, for example speed = newSpeed; is an assignment.. 64

В

body

A body is a part of an method. It is the part that is bordered by the curly braces. The whole content between these braces is called body (see header for contrast). 64

boolean expressions

A boolean expression is an expression that has only two possible values: **true** or **false**. They are often controlling conditional statements. For example an **if** (a<b) can only return a **true** or **false**. 64

class

A class describes the kind of an object. This is done by giving instance variables and methods. The objects represents individual instatioations of the class. 64

class variable

In Java a class can also have a field in contrast to fields that belong to each and every object that is created. Such a field is called class variable or static variable and exists only once for all instances of that class. 64, 67

collection

A collection can store an arbitrary number of other objects. Common variants for collections in Java are the ArrayList-Objects and arrays. 64

conditional statement

A conditional statement takes one of two possible actions based upon the result of a test. For example **if**(a<b)... **else**... is a typical conditional statement. 64

constructor

A constructor is a special method in a class which is responsible to initialize objects properly. In difference to usual methods it has no return value and is only used once. 64

\mathbf{D}

documentation

Documentation in programming is very important and nobody can achieve success in programming without a good use of documentation. In Java there are some conventions on documentation but in general the following rule is the most important: Write documentation (comments) so that you explain what something does but not how it does it. This is an important aspect of desing pattern and strategy (see information hiding). Java has a tool named javadoc that is converting source comments into a HTML formatted documentation. 64

\mathbf{F}

field

Fields store data for an object to use. Fields are also known as instance variables.. 64

C H

header

A header is a part of a method. It is the part that is not only including the signature but the whole definition. Example: **public** int getAge(String name) is the header whereas getAge(String) is the signature. 64

Ι

immutability

In Java the expression "immutable" is mostly used to describe an object. It sais that the objects state or contents cannot be changed once it's created. A common example in Java are String object which are always immutable. So in short this means that a immutable object is a unchangable or fixed object. 64

implementation

An implementation is a source code that is defining something like a class or method. Takling about methods you could say something like "this is the implementation of the method XY" pointing to a source code. The implementation is a recipe how something is actually done (recipe is a good analogy to source code). 64

information hiding

Information hiding is a principle that states that internal details of an implementation should be hidden from the user of it. This shall ensure better modularization and support abstraction. In Java this is done with the use of an access modifier like **private** or **protected**. 64

instance

An instance is a realisation of a class to a real object, so instance is a synonym to object. 64

iterface

An interface in Java is used to agree or declare signatures of methods that are shared over different classes. The interface is declaring which methods exist or have to exist. It can be used without showing the implementation. 64

iterator

An iterator is an object that provides functionality to iterate over all elements of a collection. 64

${f L}$

library

In Java a libraray is a importable collection of classes. These classes are arranged in packages. A known library is the so called Java standard class library, which contains very useful classes for almost all Java programs. 64

library documentation

The Java class library documentation shows details about all classes in the library. Using this documentation is essential in order to make good use of the library classes. 64

lifetime

The lifetime of a variable describes how long the variable continues to exist before it is destroyed. 64

local variable

A local variable is a variable declared and used within a single method. Its scope and lifetime are limited to that specific method they're defined in. A special variant of local variables are actual parameters. 64

loop

A loop is a functionality that is given by the elementary functions of a programming language, like in Java. They are used to repeat a sequence of expressions (a body) for a number of times, coupled to one or more conditions. In Java there are three essential types of loops: The **while**, **do while** and **for** loop. There are also other types of loops like the "foreach" loop. 64

\mathbf{M}

map

A map is a collection type. It stores key-value pairs as entries and it stores each individual element (key) at most once. It does not maintain any specific order. A good use for maps is a phonebook, where every key (person, name) is only once in the book. 64

method

A method is a action (function) of a specific class that can be invoked on an object of the given class. Objects usually do something when a method is invoked, so a good keyword to it would be *what*, as most methods

are named by a verb. The methods give the objects their own particular and characteristic behavior. 64

modularization

Modularization is the process of dividing a whole into well-defined parts that can be build and examined seperately and that interact in well defined ways. For example a car as a whole entitiy can be divided into modules such as the engine, seats, radio, wheels and so on. 64

mutator

A mutator or mutator method is a method that provides the ability to change fields of an object. For example changeSize(int newSize) is a typical mutator method. 64

\mathbf{N}

non-primitive types

Java has eight primitive types (boolean, char, byte, short, int, long, float, double) and gives the programmer the ability to define own types of a more complex manner. For example a class defines a new type with the name of the class. Variables that have a class as their type can store objects of that class. A popular example of such a type is String which in fact is a class. 64

null

null is a reserved word in Java (and many other programming languages) that indicates that a reference is not referencing to something, that it is showing to null. In Java it's used to mean "no object" because a reference variable should point to a object, if it's not so it's containing the reference null. Also a filed that has not been explicitly set will contain null if it's not defined by an other default value (like 0 for variables of type int).

\mathbf{O}

object

An object is a instance of a class. 64

object reference

Variables of an object type (non-primitive type) always store references to objects. 64

overloading

In Java sources, classes may contain multiple constructors, methods and variables (variable vs. parameter) with the same name. This is called overloading. In Java there is a keyword **this** to specify the variables so that the compiler can differ them plural. 64

Р

parameter

Addition information (data) given to a method or object is called parameter. 64

primitive types

The primitive types in Java are the non-object types boolean, char, byte, short, int, long, float, double. An important characteristic to primitive-types is, that they don't have methods. 64

\mathbf{R}

random number

Real or pure random numbers in computer programming are not that easy to implement, since computers operate in a well defined and deterministic way which makes them highly predictable and that way quite the opposite of everything random. A common but not equivalent alternative are so called pseudo-random numbers. These numbers are calculated by special algorithms that try to give random numbers. 64

\mathbf{S}

scope

The scope of a variable defines the section of source code from which the variable can be accessed. 64

\mathbf{set}

A set is a collection type. It stores each individual element at most once. It does not maintain any specific order. A good use for a set is to collect all used words in a string (sentence, page, book), where you want to have every word only once. 64

signature

The signature of a method is the part that identifies it to the compiler. For example

the signature of **public** setSpeed(int newSpeed, int newTolerance) is not the whole head of the method but the name setSpeed and the list of parameter-types int \dots , int \dots 64

state

A object or its status is represented by his state. The state is represented by the values in the fields (instance variables). 64

static variable

See class variable. 64

\mathbf{T}

type

The type defines the kind of data or value (for example to a parameter, return value (see data types) or a variable. 64
